

# Prime Factorization with Exponents

Name: \_\_\_\_\_ Date: \_\_\_\_\_ Score: \_\_\_\_\_ / 24

## Q Quick Review

The **prime factorization** of a whole number writes it as a product of *prime numbers* only — numbers like 2, 3, 5, 7, 11 that have no factors besides 1 and themselves. A **factor tree** helps: keep breaking a number into two factors until every branch ends in a prime. When the same prime shows up more than once, gather the copies into an **exponent**, so  $2 \times 2 \times 2 = 2^3$ . Every whole number greater than 1 has exactly *one* prime factorization, so this is like a number’s fingerprint. It also makes finding the GCF and LCM much easier.

◇ **Example:** Write the prime factorization of 72 using exponents.

⇒ Build a factor tree. Start by splitting  $72 = 8 \times 9$ . Now break each branch:  $8 = 2 \times 2 \times 2$  and  $9 = 3 \times 3$ . Every branch now ends in a prime, so  $72 = 2 \times 2 \times 2 \times 3 \times 3$ . Finally, collect the repeats into exponents — there are three 2s and two 3s — which gives  $2^3 \times 3^2$ . (Quick check:  $8 \times 9 = 72$ .)

**Answer:**  $72 = 2^3 \times 3^2$

## PRACTICE

Write the prime factorization of each number using exponents.

Collecting the two 2s gives <math>2^2 \times 3 \times 7</math>.</p> <p>22. <math>2^3 = 8</math> and then <math>8 \times 3 = 24</math>, so the number is 24.</p> <p>23. Take the highest power of each prime that appears: <math>2^2</math> and <math>3^2</math>. The LCM is <math>2^2 \times 3^2 = 4 \times 9 = 36</math>.</p> <p>24. The number 1 is not a prime number, so it should never appear in a prime factorization. The correct answer is just <math>2 \times 3 \times 5</math>.</p> |
